INTRODUCTION

North Pacific albacore (*Thunnus alalunga*) are taken by fisheries from various nations (Table 1). Japan is the largest harvester, annually taking 74% of the North Pacific albacore landed by all nations, while the U.S. annually takes less than 20%. U.S. troll vessels have fished for albacore in the North Pacific since the early 1900's (Clemens and Craig, 1965). The collection of logbook and length-frequency data from the U.S. North Pacific albacore troll fishery began in 1951. The agencies involved in the voluntary collection of logbook, length-frequency, and landings information from the U.S. albacore troll fisheries are the Southwest Fisheries Science Center (SWFSC) of the National Marine Fisheries Service (NMFS), Western Fishboat Owners Association (WFOA), Pacific States Marine Fisheries Commission (PSMFC), and the state fisheries agencies of California, Oregon, and Washington. Beginning in 1971, cooperative surveys between NMFS and the American Fishermen's Research Foundation (AFRF) lead to the expansion of albacore fishing areas to areas North of Hawaii and west of the International Dateline (Laurs, Lynn, Nishimoto, 1975). In recent years the North Pacific season has begun as early as mid-April in areas northwest of Midway Island. In July and August, the fleet fishes near 45EN, 150EW and along the West Coast from Vancouver Island to California. Fishing can continue into November if weather permits and sufficient amounts of albacore remain available to troll gear.

Japan harvests the largest proportion of albacore caught annually in the South Pacific (average of 41%). The U.S. annually takes 2% of the total landings of South Pacific Albacore. Exploratory troll fishing for albacore in areas east of New Zealand in 1986 resulted in the development of the U.S. South Pacific troll fishery (Laurs et al., 1987). The collection of logbook, landings, and length-frequency data from the U.S. South Pacific fishery began in 1987, just after that fishery's inception. This fishery takes place during the austral summer months (December through April). U.S. troll vessels that participate in the South Pacific fishery depart from the U.S. West Coast or Hawaii after the end of the North Pacific season and travel to American Samoa or French Polynesia to prepare for the South Pacific season. South Pacific fishing areas extend from the Tasman Sea to approximately 110EW between 25ES and 45ES. At

the end of the season (in March or April), most vessels unload in Pago Pago, American Samoa then travel to Hawaii or the U.S. West Coast to prepare for the next North Pacific fishing season.

This report presents summaries of the logbook (catch/effort), landings and length-frequency information collected from the 1998 North Pacific and the 1997-98 South Pacific albacore seasons. Data from the 1997 North Pacific season, 1996-97 South Pacific season, and from non-U.S. albacore fisheries (where available) are included for comparison.

DATA COLLECTED

Total annual landings data from the various fisheries that catch albacore in the Pacific Ocean are available from 1952 to 1998 (Tables 1 and 2). The SWFSC collects landings, logbook and length-frequency information from the two U.S. Pacific albacore troll fisheries and sea surface temperature (SST) information for the North Pacific fishery. Data from direct landings and at-sea transshipments are provided by the WFOA and collected from state landings receipts submitted by fish buyers and canneries. Daily catch and effort data are obtained from completed copies of the *U.S. Pacific Albacore Logbook*, that are voluntarily submitted by fishermen, or completed by port samplers who collect the information from cooperating fishermen. Approximately 800 logbooks were distributed to albacore fishermen for the 1998 North Pacific and the 1997-98 South Pacific albacore seasons. Length-frequency data from the 1998 North Pacific season were collected by port samplers in the ports of Westport and Ilwaco, Washington, Astoria, Newport, and Coos Bay, Oregon, Crescent City, Eureka, and Terminal Island, California and Pago Pago, American Samoa.

North Pacific sea surface temperatures (SSTs) recorded from commercial transport ships, fishing vessels, and research vessels, were compiled into monthly means and computer-analyzed. Contours of SSTs were drawn with a resolution of 1E latitude-longitude (Figures 2a through 2g). Analysis of SSTs shows the distribution of isotherms and the locations of ocean fronts (areas of north-south close spacing of isotherms). Insufficient SST information is available from the areas of the South Pacific fishery (east of New Zealand to 110EW and south of 30ES) to make an analysis possible.

LOGBOOK SAMPLING COVERAGE

Logbook sampling coverage is the ratio of landings from sampled trips (those trips from which logbook data were received) to total landings. Landings from sampled trips in some past seasons are not available. For consistent comparison of sampling coverage between current and past seasons, sampled landings are estimated by multiplying numbers of fish caught (recorded in logbooks) by the average weight of those fish and summing these estimates from sampled logbooks.

A total of 285 trips (of approximately 2,600 total trips) were sampled for logbook information during the 1998 North Pacific season. Sampled landings total 5,321 metric tons (t), resulting in a logbook sampling coverage rate of 36%, slightly lower than 38% in 1997 (Table 3).

Logbook data from the 1997-98 South Pacific season were collected from 34 trips of the 39 trips made by U.S. troll vessels. These sampled trips landed 1,198 t, resulting in a logbook sampling coverage of 68%, the same coverage for the 1996-97 season (Table 4).

LENGTH-FREQUENCY SAMPLING COVERAGE

Length-frequency sampling coverage is the ratio of the number of fish sampled (measured) to the total number of fish landed for the season. The total number of fish landed for the season is estimated by dividing total landings by the average weight of fish landed. The estimated total number of fish landed during the 1998 North Pacific season is 2,277,834 fish. A total of 16,505 albacore were measured, resulting in a length-frequency sampling coverage of 0.7%, significantly lower than 2.0% coverage in the 1997 North Pacific season (Table 3). Long delays in unloading and selling catches hampered samplers' efforts to obtain length-frequency samples, resulting in a decreased sampling coverage rate.

Length-frequency data for the 1997-98 South Pacific albacore fishery were collected by port samplers in Pago Pago, American Samoa. Due to the fact that the canneries in American Samoa were not purchasing albacore, most of the troll fleet sold their catch in Fiji where no length-frequency sampling was done. Samplers in American Samoa measured 200 albacore from two troll vessel landings, resulting in a length-frequency sampling coverage rate of 0.1%. The coverage rate in the 1996-97 season is 0.7% (Table 4).

TOTAL EFFORT AND CATCH

Fishing effort in the albacore troll fisheries is measured in number of fishing days. Total fishing effort for the U.S. albacore troll fisheries is estimated by dividing total landings (in pounds) by catch-per-unit effort (in numbers of fish per day) then dividing by average weight (in pounds). Troll vessels fished an estimated 20,207 days during the 1998 North Pacific albacore season, a 54% decrease in effort from 44,356 days fished in 1997 (Table 3). This large decrease in effort can be attributed to the fact that much of the fleet spent long periods in port with full loads unable to find buyers. Total landings from the 1998 North Pacific albacore season increased slightly to 14,682 t from 14,151 t landed in 1997. Total landings may have been much higher if albacore fishermen could have sold their catches faster. Estimated albacore landings by non-U.S. fisheries that target albacore in the North Pacific are listed in Table 1.

Total fishing effort for the 1997-98 South Pacific albacore fishery is estimated to be 5,604 days, an increase of 92% from 2,912 days fished in the 1996-97 season (Table 4). Total U.S. landings for 1997-98 increased slightly to 1,764 t from 1,403 t landed in 1996-97. Estimated landings by non-U.S. fisheries targeting albacore in the South Pacific are listed in Table 2.

DISTRIBUTION OF CATCHES AND SSTs

Albacore catches recorded during the 1998 North Pacific season extend from the West Coast to 170EE, between approximately 30EN and 50EN. Areas of high catch indicate productive regions where albacore are available to troll gear. Based on sampled logbook data, three high catch areas were centered at 37°N, 176EW, 42°N, 149EW and 46EN, 125EW (Figure 1). Catch areas recorded by U.S. troll vessels for each month of the 1998 North Pacific season

are shaded on corresponding monthly (SST) contour charts in Figures 2a through 2g. These figures show the relationship between fishing areas, SST fronts and isotherm patterns. The area of highest catch in May was located at 37°N, 176°W (Figure 2a). SSTs in this area ranged from xEC to xEC (xEF to xEF) and were... normal ("normal" refers to the long-term mean averaged over the past 20 years). The area of highest albacore catches in June extended between 35EN and 39EN, from 160°W to 176°W where SSTs ranged from xEC to xEC (xEF to xEF) and were xEC to xEC ... normal (Figure 2b). During July, the most productive fishing occurred between 41EN and 43EN from 146EW to 151EW in SSTs ranging from xEC to xEC (xEF to xEF, Figure 2c), which were xEC to 2EC ... normal. During July, catches ranging from 5,00 fish to 21,000 fish were distributed between 41°N and 43°N, from 146°W to 151°W. was in ... SSTs between xEC and xEC (xEF to xEF). High catches in August shifted slightly westward between 42EN to 45EN from 148EW to 152EW (Figure 2d). SSTs ranged from xEC to xEC (xEF to xEF) in this area. SSTs were ... offshore and xEC to xEC ... normal in the coastal fishing areas. In September, offshore catches were scattered. The highest albacore catches were distributed from 45°N to 47°N between 125°W and 126°W (Figure 2e). SSTs were xEC to xEC ... normal along the West Coast. Very little catch data is available from October. Two small areas with catches less than 21,000 fish were centered at 40°N, 152°W and 44°N, 126°W. in xEC to xEC (xEF to xEF) water that was about xEC ... normal (Figure 2f). Catches reported in November were centered at 38°N, 157°W. where SSTs were xEC (xEF).

Albacore catches recorded during the 1997-98 South Pacific season were summarized for the season and for each month by 5E x 5E squares (Figures 3a through 3f). The highest albacore catches of the season were between 35ES and 45ES, from 150EW to 160EW (Figure 3a). Fishing in November 1997 was distributed between 30°S and 40°S, from 170°W to 170°E (Figure 3b). Albacore catches in December 1997 were distributed from New Zealand to 150°W between 30°S and 40°S (Figure 3c). The areas where most fish were caught in January 1997 are between 35ES and 40ES from 155EW to 160EW (Figure 3d). High catches in February were located between 40ES and 45ES from 155EW to 160EW (Figure 3e). Catches in March spanned from 35°S to 45°S between 150°W and 170° (Figure 3f).

CATCH-PER-UNIT EFFORT

Catch-Per-Unit Effort (CPUE) is used as an indication of relative abundance of albacore available to troll gear, or a measure of fishing success, and is expressed in numbers of fish caught per day of fishing. Catch (in numbers of fish) and effort (in days fished) were summarized by 10-day, 1E-square strata in which there was at least one day of fishing effort (Kleiber and Perrin, 1991). Average CPUE is calculated as follows:

$$\text{Average CPUE} = \frac{\sum_{i=1}^n \frac{C_i}{E_i}}{n}$$

Where C_i is the total sampled catch in the i^{th} strata, E_i is the total sampled effort in the i^{th} strata, and n is the total number of strata.

CPUE for the North Pacific albacore troll fishery declined by approximately 50% between 1963 and 1990, but has been increasing since 1990 (Figure 4). This increasing trend is strongly influenced by the success of the offshore fishery in the late 1980's. The average CPUE for the 1998 North Pacific season increased to 113 fish per day from 46 fish per day in the 1997 season (Table 3). This increase in CPUE is due to a large reduction of effort due to marketing problems. Much of the fleet remained in port for a large portion of the season, unable to sell their catches.

CPUE for the U.S. South Pacific troll fishery declined between the 1986-87 and 1992-93 seasons (Figure 4). CPUE then peaked at 150 fish per day in 1994-95. The CPUE for the 1997-98 South Pacific season was 53 fish per day compared to 78 fish per day in the 1996-97 season (Table 4).

CPUEs from the 1998 North Pacific season were summarized (averaged) for the season and each month by 1E x 1E squares (Figures 5a to 5g). The highest CPUEs averaged for the season ranged from 230 to 781 fish per day and were distributed between 171EE and 127EW from 34EN to 46EN (Figure 5a). In May, CPUEs greater than 85 fish per day were distributed between 170EE and 174EW from 35°N to 38EN (Figure 5b). In June, CPUEs from 230 to 781 fish per day were concentrated between 162EW and 176EE from 36EN to 39EN (Figure 5c). The highest CPUEs (between 85 and 781 fish per day) in July were distributed between 145EW and 169EW from 38EN to 46EN (Figure 5d). The highest CPUEs in August were located between 139EW and 154EW from 42EN to 45EN and along the coast between 124°W and 128°W from 43°N to 47°N (Figure 5e). High CPUEs in September were scattered between 125EW and 151EW from 41EN to 47EN (Figure 5f). High CPUEs in October were concentrated between 147°W and 157°W from 38°N to 42°N and between 125°W and 128°W from 42°N to 46°N (Figure 5g). CPUEs between 85 and 230 fish per day were reported for November between 156EW and 158EW from 38EN to 39EN.

CPUEs for the 1997-98 South Pacific season were summarized (averaged) for the season and each month by 5E x 5E squares (Figures 6a through 6f). The highest CPUEs for the 1997-98 season ranged from 101 fish per day to 191 fish per day between 155EW and 160EW from 40ES to 45ES (Figure 6a). CPUEs in November 1997 ranged from 1 to 33 fish per day between 175EE and 170EW from 30ES to 40ES (Figure 6b). CPUEs increased in December 1997 with the highest CPUEs (34 to 100 fish per day) ranging between 150°W and 170°W, from 30°S to 40°S (Figure 6c). The highest CPUEs in January 1998 ranged from 34 to 100 fish per day and were distributed between 140°W and 180° as well as in the Tasman Sea (Figure 6d). In February, CPUEs exceeding 101 fish per day were distributed between 150EW and 160EW from 35ES to 50ES (Figure 6e). CPUEs decreased in March as the season began to wind down. CPUEs from 34 to 100 fish per day were located between 150EW and 170EW from 35ES to 45ES (Figure 6f).

LENGTH-FREQUENCIES

Fork lengths of albacore measured during the 1998 North Pacific season ranged from 49 cm (5 lb or 2.4 kg) to 98 cm (42 lb or 19.2 kg) and averaged 68cm (14 lb or 6.4 kg). The average fork length of sampled albacore from the 1997 season is 70 cm (15.5 lb or 7.0 kg). Two length-frequency modes are evident in the histogram of samples from the 1998 North Pacific season

(Figure 7). The most prominent mode is centered near 65 cm fork length (3 years old). A less prominent mode is centered at 83 cm (5 years old).

Small albacore (less than 49 cm fork lengths) may not be adequately represented in the length-frequency data collected from the 1998 North Pacific fishery. The larger troll vessels that fish further offshore and sell most of their catch to canneries or buying stations (which may pay less for small fish), may release small fish when they are abundant in the catches. The smaller, coastal troll vessels may sell fish direct to the public or other markets where small fish are preferred. Coastal troll vessels may retain more small fish than larger offshore vessels.

Albacore fork lengths measured during the 1997-98 South Pacific season range from 56 cm (8 lb or 3.6 kg) to 84 cm (27 lb or 12.1 kg) and average 66 cm (13 lb or 5.9 kg). The average fork length of sampled albacore from the 1996-97 season is 67cm (14 lb or 6.2 kg). At least one significant length-frequency mode is apparent in the histogram of samples from the 1997-98 season (Figure 8). It is centered at 63 cm (3-4 years old). Another, less distinct mode is centered at 72 cm (4-5 years old). It is important to note the small sample size (200 fish) for the length-frequency samples obtained from the 1997-98 South Pacific season.

Length-weight-age conversions for North Pacific albacore and length-weight conversions for South Pacific albacore were taken from "A review of the biology and fisheries for North Pacific albacore (*Thunnus alalunga*)" by Bartoo and Foreman, 1993. Length-age conversions for South Pacific albacore are taken from Labelle, et. al., 1993.

SUMMARY

Logbook sampling coverage for the 1998 North Pacific albacore fishery decreased slightly to 36% from 38% in 1997. Length-frequency sampling coverage dropped to 0.7% in 1998 due to problems in obtaining length-frequency samples. Total effort by U.S. troll vessels in 1998 decreased 54% to 20,207 days. U.S. troll vessels landed a total of 14,682 t during the 1998 North Pacific season. The season began in May north of Midway Island and ended in November. Albacore catch locations ranged from the West Coast to 170EE. The highest reported catches during the season were centered at 37°N, 176°W, 42EN, 149EW, and 46EN, 125EW. The most productive fishing areas followed the sub-arctic ocean front delineated by 15EC and 18EC isotherms (59.0EF and 64.4EF, respectively) in the offshore areas and were found near fronts caused by upwelling in coastal areas. The average CPUE for the 1997 season increased from 46 fish per day in 1997 to 113 fish per day. The large increase is attributed to a large decrease in effort due to vessels being unable to sell their catches during the peak of the season. Season-averaged CPUEs between 230 and 781 fish per day were distributed between 171EE and 127EW from 34EN to 46EN. A total of 16,505 albacore were measured during the 1998 North Pacific season. Fork lengths of sampled albacore range from 49 cm to 98 cm and averaged 68 cm. The histogram of length-frequency samples from the 1998 season show two modes centered at 65 cm, 83 cm. Fish less than 49 cm fork length may not be adequately represented in the North Pacific length-frequency samples due to releasing of small fish.

Logbook sampling coverage for the 1997-98 South Pacific albacore troll fishery remained the same as the 1996-97 season at 68%. Length-frequency sampling coverage is 0.1%. Since most vessels unloaded in Fiji where no length-frequency sampling was done. Total effort

by U.S. troll vessels in the South Pacific increased 92% to 5,604 days in the 1997-98 season. U.S. troll vessels landed 1,764 t of albacore during the 1997-98 South Pacific season. The 1997-98 season began in November 1997 and ended in April 1998. The most productive areas were between 35ES and 45ES, from 150EW to 160EW. The average CPUE for the 1997-98 season is 53 fish per day, compared to 78 fish per day in the 1996-97 season. Season-averaged CPUEs ranging from 101 fish per day to 191 fish per day were distributed between 155EW and 160EW from 40ES to 45ES. A total of 200 albacore were measured during the season. Fork lengths of measured fish range from 56 cm to 84 cm and averaged 66 cm. At least one prominent mode is centered at 63 cm in the length-frequency histogram of sampled fish.

ACKNOWLEDGMENTS

We thank the albacore fishermen whose participation in the logbook sampling program make this report possible. The American Fisherman's Research Foundation and the WFOA provided landings data and financial support for keypunching of the logbook and length-frequency data. Rhonda Haynes (Oregon Department of Fish & Wildlife), Marija Vojkovich (California Department of Fish & Game), Wendy Beeghley-White (Washington Department of Fisheries), Russell Porter (Pacific Marine States Fisheries Commission), and Gordon Yamasaki (SWR office in Pago Pago, America Samoa) coordinated the collection of logbook, length-frequency, and landings data and provided other fishery data. We also thank the port samplers for their efforts in collecting logbook, length-frequency and landings information and for distributing the *U.S. Pacific Albacore Logbook* as well as this report.

We thank William Shaw of the Department of Fisheries & Oceans, Canada, Rodolfo Serra of Instituto de Fomento Pesquero, Chile, Dr. Yuji Uozumi of National Research Institute of Far Seas Fisheries, Japan, Dr. Chien-Chung Hsu of National Taiwan University, Taiwan and many other foreign colleagues for providing landings information of albacore fisheries from their respective countries.

Roy Allen and Henry Orr (SWFSC) produced the illustrations for this report. Michelle DeLaFuente typed and formatted the manuscript and tables. Atilio Coan, Jr., Dr. Norman Bartoo, ... provided helpful directions, comments and critiques of the manuscript.

¹ Data are from the 15th North Pacific Albacore Workshop, December 3-5 1997, Nanaimo, B.C., Canada except as noted.

² Japanese pole & line landings include fish caught by research vessels. Longline landings for 1952-1960 exclude minor amounts taken by vessels under 20 metric tons.

³ Korean longline landings calculated from Y. Gong (pers. comm.) using the ratio of landings, in numbers, from the North Pacific. Gillnet landings for 1979-1990 are calculated by multiplying the 1991 CPUE (# fish per pok) by effort (# poks) then multiplying by average weight (1991, 1992: 4.13 kg/fish).

¹ Data are from Twelfth Meeting of the Standing Committee on Tuna and Billfish, 16 June - 23 June 1999 except All landings are from areas within the SPAR statistical area except as noted.

² Japan long line include catches from Australia-Japan joint venture vessels.

³ 1982 - 1993 United States long line landings from Pelagic Fisheries of the Western Pacific Region 1996 Annual (Total landings for all gears).

⁴ United States troll landings may include catches from December of the previous year.

⁵ Australia troll 1970 - 1980 are incidental catches from pole-and-line vessels targeting southern bluefin tuna. 1981- include recreational catches.

⁶ Chile gill net landings from R. Serra (pers. comm.).

⁷ Other includes Cook Islands, Papua New Guinea, and China. China longline landings from SPC Tuna Fishery

⁸ Other includes Canada, Fiji, Cook Islands, Belize, Sweden, Tonga, and Ecuador.
